### Access Specifiers

We can add another public method in order to get the value of the attribute.

```

class myClass {
public:
    void setName(string x) {
        name = x;
    }
    string getName() {
        return name;
    }
private:
    string name;
};

```

The `getName()` method returns the value of the private `name` attribute.

Operator Overloading
XP 295

4/4

### Operator Overloading

We need our `+` operator to return a new `MyClass` object with a member variable equal to the sum of the two objects' member variables.

```

class MyClass {
public:
    int var;
    MyClass() {}
    MyClass(int a) : var(a) {}

    MyClass operator+(MyClass &obj) {
        MyClass res;
        res.var= this->var+obj.var;
        return res;
    }
};

```

Here, we declared a new `res` object. We then assigned the sum of the member variables of the current object (`this`) and the parameter object (`obj`) to the `res` object's `var` member variable. The `res` object is returned as the result.

This gives us the ability to create objects in main and use the overloaded `+` operator to add them together.

7/7

What is the keyword for overloading an operator in C++?

operator

Correct!

## Classes & Objects

OOP is a programming style that is intended to make thinking about programming easier - to thinking about the real world.

Class: Objects are created with classes, which are actually the focal point of OOP.

Class describes what the object is, but is separate from the object itself.

ex: Name: BankAccount  
Attribute: account number, balance, date opened  
Behaviour: open(), close(), deposit()

ex: class BankAccount {  
};

ex: class BankAccount {  
public: void sayHi() {  
cout << "Hi" << endl;  
}  
};

## Abstraction

Data abstraction is the concept of providing only essential information to the outside world.

## Encapsulation

more than simply combining attributes and behaviour together with in a class; it also means restricting access to the inner workings of that class.

Black-boxing which refers to closing the inner workings of the object, except of the piece that want to make public.

## ex

access specifier.

```
#include <iostream>
#include <string>
using namespace std;
class MyClass {
public: string name;
};

int main() {
    MyClass myObj;
    myObj.name = "soiolearn";
    cout << myObj.name;
    return 0;
}
```

private: cannot be accessed or viewed.

public: member may be used to access private.

```
#include <iostream>
```

```
#include <string>
```

```
using namespace std;
```

```
class myclass {
```

```
public:
```

```
void setname (string x) {
```

```
name = x;
```

```
}
```

```
private:
```

```
string name;
```

```
};
```

```
int main() {
```

```
myclass myobj;
```

```
myobj.setname ("John");
```

```
return 0;
```

```
}
```

Remember to access name.

from public can make use  
of setname() → in public!

ex.

```
public:
```

```
void setname (string x) {
```

```
name = x;
```

```
}
```

```
string getname () {
```

```
return name;
```

```
}
```

```
private:
```

```
string name;
```

```
};
```

getname() method returns  
the value of private name  
attribute.

### Constructors

They are created & executed  
when ever new objects are  
created within that class  
class myclass {

```
public:
```

```
myclass () {
```

```
cout << "hey";
```

```
} void setname (string x) {
```

```
name = x;
```

```
}
```

```
string getname () {
```

```
return name;
```

```
}
```

```
private:
```

```
string name;
```

```
}
```

```
int main() {
```

```
myclass myobj;
```

```
return 0;
```

```
}
```

useful for setting initial values

```
class myclass {
```

```
public:
```

```
myclass (string name) {
```

```
setname (name);
```

```
} void setname (string x) {
```

```
name = x;
```

```
} string getname () {
```

```
return name;
```

```
} private:
```

```
string name;
```

```
}
```

```
int main() {
```

```
myclass obj ("David");
```

```
myclass obj2 ("Amy");
```

```
cout << obj.getname();
```

```
}
```

### More on class

Creating a new class

Source & header

header file (.h) holds the function  
declarations (prototypes) & variable  
declarations

default constructor:- myclass.h

```
#ifndef MYCLASS_H
```

```
#define MYCLASS_H
```

```
class myclass
```

```
{ public:
```

```
myclass ();
```

```
protected:
```

```
private:
```

```
};
```

### Destructor

They're called when an object  
is destroyed or deleted

```
class myclass {
```

```
public:
```

```
~myclass () {
```

```
// some code
```

```
}
```

```
#include "myclass.h"
```

```
#include <iostream>
```

```
using namespace std;
```

```
myclass::myclass ()
```

```
{ cout << "constructor" << endl;
```

```
}
```

```
myclass::~myclass ()
```

```
{ cout << "Destructor" << endl;
```

```
}
```

### Member function

```
#include "myclass.h"
```

```
#include <iostream>
```

```
using namespace std;
```

```
myclass::myclass ()
```

```
{
```

```
void myclass::myprint () {
```

```
cout << "Hello" << endl;
```

```
}
```

### Pointers

```
myclass obj;
```

```
myclass * ptr = &obj;
```

```
ptr->myprint();
```

### Constant object

```
const int x = 42;
```

### Compilation

```
class person {
```

```
public:
```

```
person (string n, int d, int b)
```

```
{ name(n), b(d)
```

```
} private:
```

```
string name;
```

```
int birthday;
```

```
}
```

every object in C++ has access

to its own address through

an important pointer

called this pointer

## Random Numbers

Pseudo random number generator function that calls rand()

when used we are required to include <stdlib.h>

```
#include <iostream>
#include <cstdlib>
using namespace std;
int main() {
```

```
    cout << rand();
```

```
}
```

srand() function is used to generate truly random numbers.

this allows to specify a seed value as its parameter which is used for rand()

```
int main() {
    srand(98);
    for (int x=1; x<=10; x++) {
        cout << 1+(rand() % 6) <<
        endl;
```

```
    }
}
```

this makes use of time() function to get the number of seconds on your system then randomly seed the random function.

## Default values

### function over loading

#### Function

A recursive function in C++ is a function that calls itself.

$$4! = 4 \times 3 \times 2 \times 1 = \underline{24}$$

### Pass by Reference with Pointers

#### Function arguments:-

there are two ways to pass arguments to a function as the function being called.

By value:

By reference:

X → X → X
